

## N0.1 Find the trace of $R_m$

$\text{trace}_{R_m} = 7.0000$

### Plot $R_m$

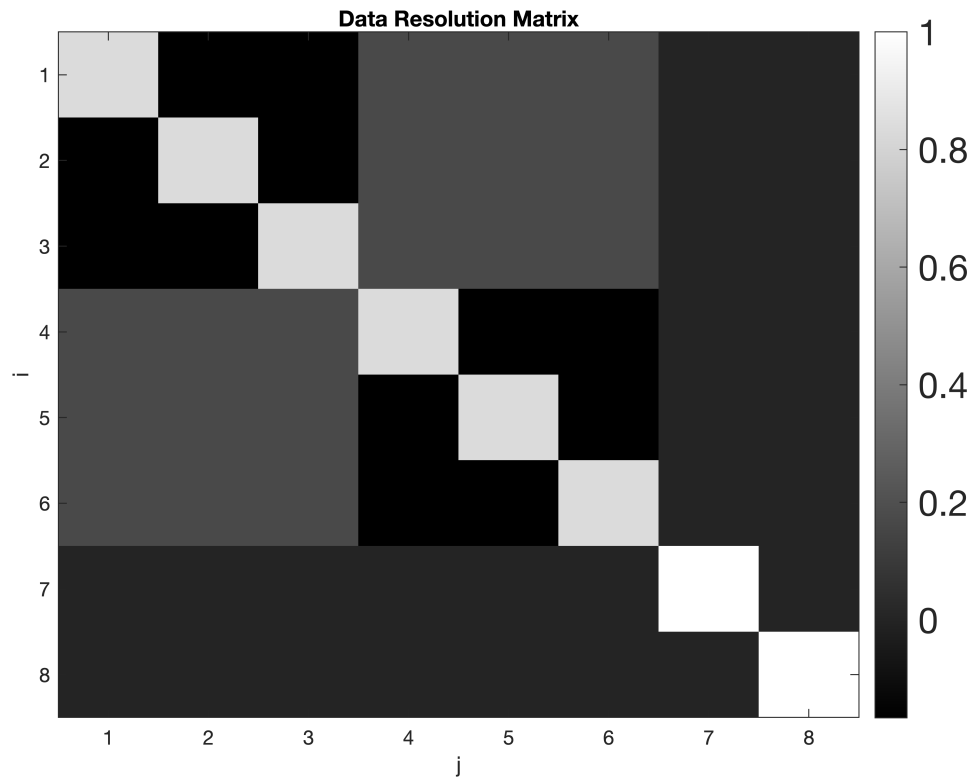

### Discuss how good the model resolution is.

Based on the model resolution matrix plot, and the  $R_{m\text{diag}}$  matrix below, it's clear that  $m_9$  is 1, hence it is perfectly resolved, however we can expect loss of resolution as a result of smearing the true model into other off-diagonal blocks as shown in the figure above. The  $\text{trace}(R_m)$  not being equal to  $n=9$  also exposes the fact that the true model is not perfectly resolved.

$R_{m\text{diag}} = 3 \times 3$

0.8333	0.8333	0.6667
0.8333	0.8333	0.6667
0.6667	0.6667	1.0000

### N0.2 Plot $R_d$

**find the trace of  $R_d$**

`trace_Rd = 7.0000`

**Discuss how good the data resolution is**

According to the plot of  $R_d$  above and the Rddiag matrix below, it shows that the last two data points are perfectly resolved, and also the remaining diagonal points of  $R_d$  as they are near 1, however, there is loss of resolution in off diagonal elements due to true data being smeared to other blocks. The  $\text{trace}(R_d)$  being not close to  $m=8$ , also exposes poor data resolution.

`Rddiag = 2x4`

```
verify = logical
0
```

## Calculate the norm

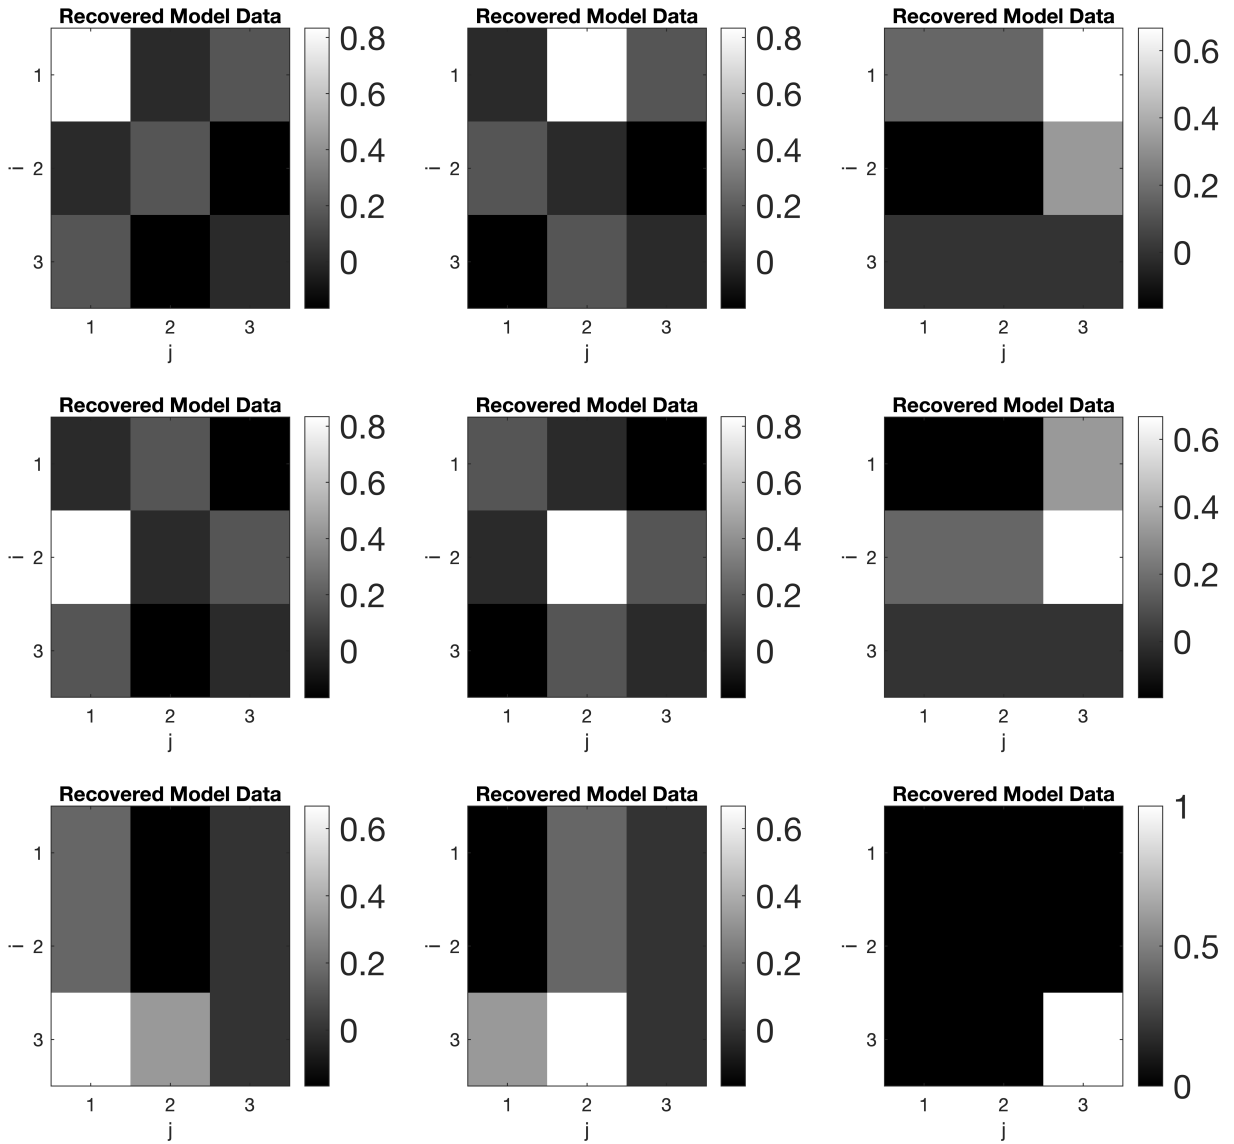

```
Norm_bias = 1.0000
```

## Discuss how this matrix gives an indication of the bias in parameter estimates.

The  $\text{norm}(R_m - I)$  must be approximate to  $(\text{trace}(R_m) - n)$  to quantify bias in the parameter estimates, however for this example  $\text{norm}(R_m - I) = 1$  and  $\text{trace}(R_m) - n = -2$ , which are not equal, hence there is no bias in the parameter estimates.

```
t_rm = -2.0000
```

## N0.4 Plot the recovered models.

### Conclusion about the smearing of the parameter estimates due to limited data resolution.

It causes data about the central block slowness to smear into some but not all of the adjacent blocks with the exact form of smearing depicted in the model resolution matrix.

### N0.5 Find the condition numbers of $G$ and $G^\dagger$

$$C_G = 2.8063e+16$$

$$C_{G^\dagger} = 3.0889e+16$$

### Stability of model parameter estimates in relation to condition numbers of $G$ and $G^\dagger$

Since the condition number for both  $G$  and  $G^\dagger$  are big, then it means that model parameteres produced by using both  $G$  and  $G^\dagger$  are instable, since we have a significant parameter change dipicted from the fact that in both scenarios,  $s_1 \gg s_p$ , producing very large condition numbers, hence telling as that we are dealing with an ill-conditioned problem.
